Conda vs Anaconda vs Miniconda

- Questions to audience:
- How many here use any conda-based system?
- How many understand the differences between the different conda terms in the title of this slide?
- Before we expunge/reinstall, let's understand it better.

Conda vs Anaconda vs Miniconda (2)

Miniconda is a minimal set of packages, to be expanded by the advanced user.

Standard conda package (grey)

Conda also manages virtual envs

- If you only ever need one environment, you could stay with graphical Conda installer, however...

conda create -n py37 python=3.7 spiceypy matplotlib numpy

spiceypy

py37

matplotlib

numpy

...and all
packages
required
for these.

Legacy Python:

```
conda create -n py2 python=2  
python2_package
```

Use “**conda activate <env-name>**”
to switch between environments.

My python package search tree

- First conda: `conda install <pkg_name>`
 - The dependency resolver will tell if it would lead to downgrades of other packages, you can inspect and reject at this point.
- What if a Python package is not available conda?
 - `pip install pkg_name`
 - **NOTE: Always do conda activate <env_name> before this (or anything really).** Because otherwise a different “pip” command might be used on your computer and install goes somewhere else.
 - Pip ALWAYS depends on current active conda environment (or PATH if no conda)
 - If you ever did “pip install” and then Python couldn’t find it, it didn’t install where you think it did.
- What if pkg not even on Pypi server? Find it on GitHub:
 - `git clone <url_copied_from_GitHub> && cd <cloned_repo> && pip install (-e) .`
- I use this mix for many years successfully.

Conda vs Anaconda vs Miniconda (3)

- So, in summary:
 - conda is the **executable** that manages packages (not only Python, e.g. HDF binaries, FORTRAN, OpenCV, GDAL libraries etc.)
 - “miniconda” is a minimum set of packages for proper operation of conda, installed into a “base”. **Use this if you understand conda well.**
 - “anaconda” is a meta-package with a huge list of scientific packages (dependencies) (**Recommended for beginners**)
 - Hence: **after installing miniconda and executing “conda install anaconda”, you would have the same python env as somebody that DL-ed the Anaconda distribution.**

Everyday conda (terminal) tips

- If you have installed it before, and it's older than conda 4.6, remove and reinstall everything.
 - New version (now at 4.8.x) is much faster in adding a new package
 - Too many changes that make it better to delete "old cruft"
- If you still have changed PATH changes that point to your conda install in your ba/c/tc-sh configs, remove it!
 - Call of "conda init <shell_name>" configures things correctly, adding an init section to config files.
 - Leaving the manual PATH change in can create problems.
- Advise: Don't use the initial conda "base" environment for general work.
 - Eventually some of your installs (or Anaconda, Inc.) will mess up something.
- Always create a new default environment:
 - `conda create -n py37 python=3.7`
 - `conda activate py37`
- Find packages:
 - `conda search <package_name>`
 - If list shows what you need:
 - `conda install <package_name>` (will also drag in dependencies)

Conda channels

- Channels are different locations/sources for packages.
- By default, an env is pointed to the default channel, you can confirm like so:
- The top-most channel has the highest priority for package searches.

```
$ conda config --show-sources
==> /Users/klay6683/.condarc <==
pinned_packages: []
report_errors: True
anaconda_upload: True

==> /Users/klay6683/miniconda3/envs/py37/.condarc <==
pinned_packages:
  - conda-forge::bokeh
  - conda-forge::opencv
  - conda-forge::gdal
  - conda-forge::numpy
channels:
  - conda-forge
  - defaults
```

Conda channels (2)

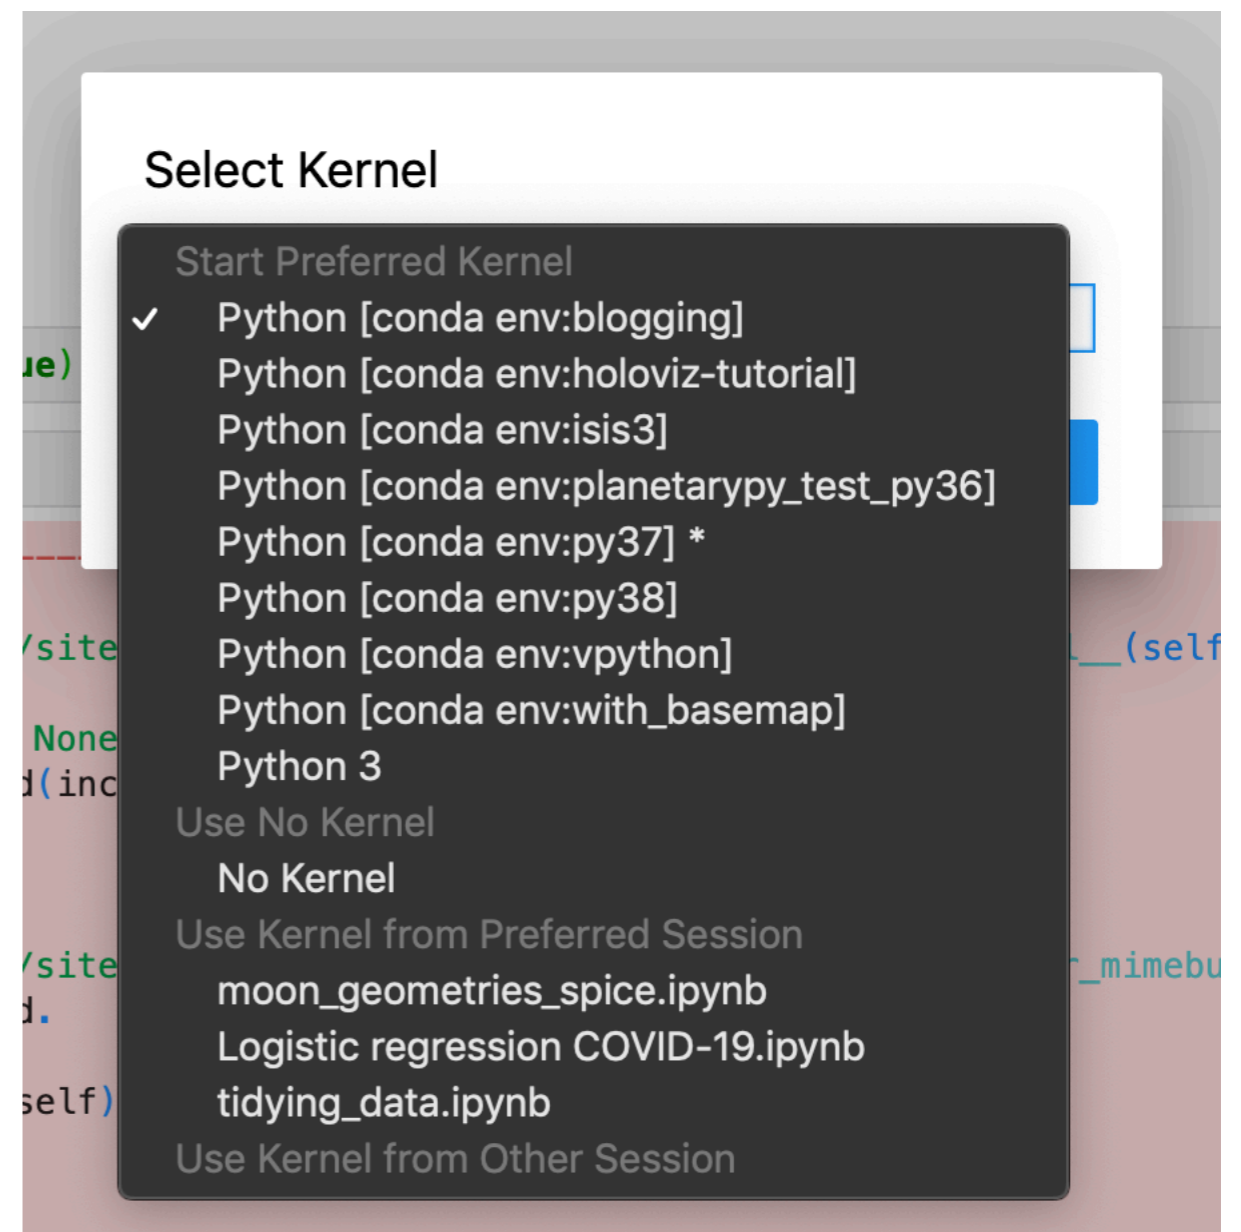

- What if you want to have one environment pointing to defaults and one to try out conda-forge?
 - -> ENV-dependent configuration!
- Activate the env you want to configure, then:
 - `conda config --env --add channels conda-forge`
- Good tip: Don't mix channels within one env. And pin packages to be sure.

Pinning packages

- Because conda sometimes finds “better” packages at default, conda did sometimes mix from different channels.
- To avoid this (catastrophic for gdal), pin packages per env to your desired channel:
 - `conda config --env --add pinned_packages conda-forge::gdal`

nb_conda_kernels

- If you are working mostly in Jupyter and (anticipate to) have more than one conda env, this is the most important conda package.
 - It finds your existing conda envs at every launch of a Jupyter server
 - It then offers kernel for each conda env in the list
- JNotebook: find menu “Kernel->change kernel”
 - JLab: click on kernel name in the upper right

How to reinstall env in 5 min

- Even a “stable” env is rotting at some point
- The trick is to have:
 - File with a list of your conda packages
 - File with a list of your pip packages
 - If you develop new packages: file with a list of your own package folders and GH installs
- a (couple of) bash script(s)

How to reinstall env in 5 min(2)

```
#!/bin/bash
```

```
./Users/klay6683/miniconda3/etc/profile.d/conda.sh
```

```
if [ "$#" -ne 2 ]; then
    echo "Usage: $0 conda_env_name python_version_string (e.g. 3.7)" >&2
    exit 1
fi
if [ -n $CONDA_DEFAULT_ENV ]
then
    if [ "$CONDA_DEFAULT_ENV" == "$1" ]
    then
        echo "Deactive $1 environment first." >&2
        exit 1
    fi
fi
```

```
conda env remove -n "$1" -y
```

```
conda create -n "$1" -y -c conda-forge python="$2"
```

```
conda install -n "$1" -y -c conda-forge --file python_stuff/standard_py3_conda_packages.txt
```

- conda deactivate
- ./reinstall_env.sh py37 3.7
- conda activate py37
- ./install_my_libs.sh

```
1 v #!/bin/sh
2 # reinstall all my packages
3 cd ~/Dropbox/src
4 v for folder in 'pyciss' 'planet4' 'pyuvis' 'hirise_tools' 'nbtools' 'planetpy' 'pysis' 'p4terrains';
5     do cd $folder;
6         echo "Installing $folder";
7         echo;
8         pip install -e .;
9         cd .. ;
10        echo;
11    done
12 # reinstall packages from pip that are needed
13 pip install -r pip_packages_to_install.txt
14
```
